

EVALUATION OF p + ³¹P CROSS SECTIONS FOR THE ENERGY
RANGE 1 to 150 MeV

M. B. Chadwick, and P. G. Young
10 December 1997

This evaluation provides a complete representation of the nuclear data needed for transport, damage, heating, radioactivity, and shielding applications over the incident proton energy range from 1 to 150 MeV. The evaluation utilizes MF=6, MT=5 to represent all reaction data. Production cross sections and emission spectra are given for neutrons, protons, deuterons, tritons, alpha particles, gamma rays, and all residual nuclides produced (A>5) in the reaction chains. To summarize, the ENDF sections with non-zero data above are:

- MF=3 MT= 2 Integral of nuclear plus interference components of the elastic scattering cross section
- MT= 5 Sum of binary (p,n') and (p,x) reactions
- MF=6 MT= 2 Elastic (p,p) angular distributions given as ratios of the differential nuclear-plus-interference to the integrated value.
- MT= 5 Production cross sections and energy-angle distributions for emission neutrons, protons, deuterons, and alphas; and angle-integrated spectra for gamma rays and residual nuclei that are stable against particle emission

The evaluation is based on nuclear model calculations that have been benchmarked to experimental data, especially for n + ³¹P and p + ³¹P reactions (Ch98). We use the GNASH code system (Yo92), which utilizes Hauser-Feshbach statistical, preequilibrium and direct-reaction theories. Spherical optical model calculations are used to obtain particle transmission coefficients for the Hauser-Feshbach calculations, as well as for the elastic proton angular distributions.

Cross sections and spectra for producing individual residual nuclei are included for reactions. The energy-angle-correlations for all outgoing particles are based on Kalbach systematics (Ka88).

A model was developed to calculate the energy distributions of all recoil nuclei in the GNASH calculations (Ch96a). The recoil energy distributions are represented in the laboratory system in MT=5, MF=6, and are given as isotropic in the lab system. All other data in MT=5, MF=6 are given in the center-of-mass system. This method of representation utilizes the LCT=3 option approved at the November, 1996, CSEWG meeting.

Preequilibrium corrections were performed in the course of the GNASH calculations using the exciton model of Kalbach (Ka77, Ka85), validated by comparison with calculations using Feshbach, Kerman, Koonin (FKK) theory [Ch93]. Discrete level data from nuclear data sheets were matched to continuum level densities using the formulation of Ignatyuk et al. (Ig75) and pairing and shell parameters from the Cook (Co67) analysis. Neutron and charged-particle transmission coefficients were obtained from the optical potentials, as discussed below. Gamma-ray transmission

coefficients were calculated using the Kopecky-Uhl model (Ko90).

SPECIFIC INFORMATION CONCERNING THE P-31 EVALUATION

For incident neutrons the Wilmore-Hodgson [Wi64] optical potential was used below 20 MeV and the Madland medium [Ma88] energy potential was used at higher energies. Above 130 MeV the reaction cross section, and corresponding transmission coefficients, were renormalized to agree with the evaluated reaction cross section of [Ch96b]. For incident protons the Becchetti-Greenlees [Be69] potential was used below 20 MeV, and the Madland potential at higher energies. Above 6 MeV the reaction cross section (and trans. coeff.) was renormalized to values predicted by the systematics of Wellisch [We96]. The potential of Lohr (Lo74) was used for deuterons, and Mcfadden-Satchler (Mc66) for alpha particles. We followed ref. [Ch96b] in ignoring He-3 emission.

Nuclear level densities were obtained using the Ignatyuk model (Ig75), and low-lying levels were obtained after first determining the upper limit for which the experimental level information is complete.
